Moment of Inertia © BinaryPhi

Last Edit: June 27, 2022 PDT

Definitions:

Moment of Inertia, often denoted by I (SI Unit: $\mathrm{kg}\cdot\mathrm{m}^2$), is a quantitative measurement of the inertia for an object to rotate about a specific axis. It can be calculated by the summation of moment of inertia of every infinitesimal part of the rigid body ($\Longrightarrow$ in other words, a **mass point**). The moment of inertia of a mass point is:

$$I = m\,r^2, \tag{1}$$

where m is the mass of the mass point and r is the distance between this mass point and the rotational axis. By using summation, the moment of inertia of a system can be written as:

$$I = \sum_{i}^{\infty} m_i\,r_i^2. \tag{2}$$

By using integral, the moment of inertia can be written as:

$$I = \int r^2 dM. \tag{3}$$

Depending on the circumstances, we can transform (3) to the following:

$$I = \int \rho r^2 dV; \tag{4}$$

$$I = \int \sigma r^2 dS; \tag{5}$$

$$I = \int \lambda r^2 dL. \tag{6}$$

In (4) (5) (6), the convention is ρ denotes the Volume Density, σ denotes the Area Density, and λ denotes the Linear Density. In addtion,

$$dL = Rd\theta$$

is also useful in some cases.

Eq.1: **Infinite Thin Rod** : **Center** (Mass: **m**; Lenght: **l**)

$$I = \frac{1}{12}ml^2. \tag{7}$$

proof

$$\begin{aligned}
I &= \int r^2 dM = \int_0^m r^2 dM \\
&= \int r^2(\lambda dL) = \int_{-l/2}^{l/2} \frac{m}{l} L^2 dL \\
&= \frac{m}{l}\int_{-l/2}^{l/2} L^2 dL = \frac{m}{l}\cdot\left[\frac{1}{3}L^3\right]_{-l/2}^{l/2} \\
&= \frac{m}{l}\left[\frac{1}{3}\left(\frac{l}{2}\right)^3 - \frac{1}{3}\left(-\frac{l}{2}\right)^3\right] \\
&\boxed{= \frac{1}{12}ml^2.}
\end{aligned}$$

Eq.2: **Infinite Thin Rod** : **One End** (Mass: **m**; Lenght: **l**)

$$I = \frac{1}{3}ml^2. \tag{8}$$

proof

$$\begin{aligned}
I &= \int r^2 dM = \int_0^m r^2 dM \\
&= \int r^2(\lambda dL) = \int_0^l \frac{m}{l} L^2 dL \\
&= \frac{m}{l}\int_0^l L^2 dL \\
&= \frac{m}{l}\cdot\left[\frac{1}{3}L^3\right]_0^l = \frac{m}{l}\left(\frac{1}{3}l^3 - 0\right) \\
&\boxed{= \frac{1}{3}ml^2.}
\end{aligned}$$

Theorem.1: Parallel Axis Theorem

The moment of inertia of a rigid body about a rotating axis is:

$$I = I_{cm} + md^2. \tag{9}$$

I_{cm} is the moment of inertia when rotating about the axis that passes through the center of mass. d is the distance between an arbitrary rotational axis and the axis that passes through the center of mass of the object.

proof

For the sake of simplicity, let's imagine the rigid body rotating about the z-axis, which passes through the center of mass of the body. You could use tensor to do a more generalized proof (I will do a tensor version of this whole topic if I have time).

$$\begin{aligned}
I_{cm} &= \int r^2 dM \\
&= \int (x^2 + y^2 + z^2) dM = \int (x^2 + y^2) dM \\
I &= \int \left((x - d_1)^2 + (y - d_2)^2\right) dM \\
&= \int \left(x^2 + y^2 - 2d_1 x - 2d_2 y + d_1^2 + d_2^2\right) dM \\
&= \int (x^2 + y^2) dM + (d_1^2 + d_2^2) \int dM \\
&\qquad - 2d_1 \int x dM - 2d_2 \int y dM \\
\because \qquad & \int x dM = \int y dM = 0 \\
\therefore I &= \int (x^2 + y^2) dM + d^2 \cdot \int dM \\
& \boxed{= I_{cm} + md^2}
\end{aligned}$$

Eq.3: Circular Thin Loop : Orthogonal Center (Mass: **m**; Radius: **R**)

$$I_z = mR^2. \tag{10}$$

proof

$$\begin{aligned} I_z &= \int r^2 dM = \int R^2 dM \\ &= R^2 \int dM = R^2 \cdot m \\ &\boxed{= mR^2} \end{aligned}$$

Eq.4: Circular Thin Loop : Diameter (Mass: **m**; Radius: **R**)

$$I_x = I_y = \frac{1}{2}mR^2. \tag{11}$$

proof

$$\begin{aligned} I_x = I_y &= \int r^2 dM \\ &= \int r^2(\lambda dL) = \int_0^{2\pi} r^2 \left(\frac{m}{2\pi R} R d\theta\right) \\ &= \int_0^{2\pi} (R\cos\theta)^2 \left(\frac{m}{2\pi}\right) d\theta \\ &= R^2 \frac{m}{2\pi} \int_0^{2\pi} \cos^2\theta d\theta \\ &= R^2 \frac{m}{2\pi} \int_0^{2\pi} \frac{1+\cos 2\theta}{2} d\theta \\ &= R^2 \frac{m}{2\pi} \left(\left[\frac{1}{2}\theta + \frac{1}{4}\sin 2\theta\right]_0^{2\pi}\right) \\ &= R^2 \frac{m}{2\pi} (\pi - 0 + 0 - 0) \\ &\boxed{= \frac{1}{2}mR^2.} \end{aligned}$$

Theorem.2: Perpendicular Axis Theorem

For a flat, thin, and uniform object, the moment of inertia, I_z, about a rotating axis, say z-axis, that is orthogonal to the center of mass, is equal to the sum of the moments of inertia of the object about two other rotating axes orthogonal to each other, I_x, I_y:

$$I_z = I_x + I_y. \tag{12}$$

I_z is the moment of inertia when rotating about the z-axis, I_x, I_y are the moments of inertia when rotating about the x-axis and y-axis respectively. Note that the object is flat among the xy surface. We have:

$$I_z = 2I_x = 2I_y; \quad I_x = I_y \tag{13}$$

when the rigid body has rotational symmetry in xy surface.

proof

$$\begin{aligned}
I_z &= \int r^2 dM \\
&= \int (x^2 + y^2) dM \\
&= \int x^2 dM + \int y^2 dM \\
&= I_y + I_x. \\
\text{Note that: } &\int x^2 dM = I_y, \\
\text{and } &\int y^2 dM = I_x.
\end{aligned}$$

Since the circular loop is a flat, thin, and uniform rigid body, we have:

$$(10) : I_z = mR^2$$

$$(11) : I_x = I_y = \frac{1}{2}mR^2$$

which satisfy

$$I_z = I_x + I_y.$$

Eq.5: Circular Thin Disk : **Orthogonal Center** (Mass: **m**; Radius: **R**)

$$I_z = \frac{1}{2}mR^2. \tag{14}$$

proof

$$\begin{aligned}
I_z &= \int r^2 dM = \iint r^2(\sigma dA) \\
&= \int_0^R \int_{-\pi}^{\pi} r^2 \sigma r d\theta dr = \int_0^R \sigma r^3 \left(\int_{-\pi}^{\pi} d\theta\right) dr \\
&= 2\pi\sigma \int_0^R r^3 dr \\
&= 2\pi\sigma \left[\frac{1}{4}r^4\right]_0^R = 2\pi \frac{m}{\pi R^2}\left(\frac{1}{4}R^4 - 0\right) \\
&\boxed{= \frac{1}{2}mR^2}
\end{aligned}$$

Eq.6: Cylinder : **Orthogonal Center** (Mass: **m**; Radius: **R**; Hight: **H**)

$$I_z = \frac{1}{2}mR^2. \tag{15}$$

proof

$$\begin{aligned}
I_z &= \int r^2 dM = \int r^2(H dM_A) \\
&= \iint r^2(H\sigma dA) = H\sigma \int_0^R r^3 \cdot 2\pi \cdot dr \\
&= H\frac{m}{\pi R^2 H} 2\pi \int_0^R r^2 r dr \\
&= \frac{2m}{R^2}\left(\frac{1}{4}R^4\right) \\
&\boxed{= \frac{1}{2}mR^2}
\end{aligned}$$

Eq.7: Circular Thin Disk : Diameter (Mass: **m**; Radius: **R**)

$$I_x = I_y = \frac{1}{4}mR^2. \tag{16}$$

proof

$$I_x = I_y =$$

$$\boxed{= \frac{1}{4}mR^2}$$
